Sudanese plants

ABSTRACT

The present study aimed at reviewing Sudanese medicinal plants screened for antifungal activity. A total of 85 plant species belonging to 48 families (42 dicotyledonous and 6 monocotyledonous) were reported to have antifungal activity against some fungal species. The family Fabaceae was reported to be the most screened family, while *Acacia nilotica* from the same family and subfamily Mimosoideae was reported to be the most screened species. On the other hand, a total of 20 fungal species belonging to 10 genera and 6 families were reported to be used in studies for antifungal activities from Sudanese plants, with the two genera *Aspergillus* and *Candida* being the most tested genera. Four methods for testing antifungal activities of Sudanese plants were used, with the cup-plate diffusion method being the most applied method (75.18%). It is hoped that this review will define the current situation of research for antifungal activities of Sudanese plants.

1. Introduction

Since time immemorial, plants have been the integral part of the healthcare system, ancient fossil records showed that a medicinal plant called Hollyhock (*Alcea rosea*) have been used since 60 000 years ago in present-day Iraq (Cowan, 1999). Medicinal plants are considered as the largest pharmaceutical stores on earth because they can produce an endless secondary phytochemical metabolites of bioactive properties which can be used effectively against various illnesses, and this was well understood and utilized by ancient civilizations (Abdallah, 2011). In the current era, although synthesized drugs are widely used in the modern medicine, the case differs in developing countries, where up to 80% of people there are still rely on traditional medicine for their health care needs, mostly plant drugs (Cunningham, 1997). Fungi considered as the second major part of biodiversity after insects, with up to 1.5 million species and only 400 species are known as animal and human pathogens (Razzaghi-Abyaneh and Rai, 2013).

The discovery of antifungal agents are much difficult than bacteria, since fungal cell wall mostly contains chitin and other polysaccharides which obstruct the antibiotics activity (Sasidharan et al., 2012), the similarity between the fungal cells and the mammalian cells could lead to toxicity of animal and human treated with these antifungal drugs (Scorzoni et al., 2016). The opportunistic fungi, particularly *Aspergillus*, *Candida* and *Cryptococcus* species, are life-threatening infections for the immune-compromised patients with AIDS, cancer or organ-transplant (Yang et al., 2006). On the other side, the fungal plant diseases are increasing, representing more than 70% of the crop diseases and threatening so many agricultural and horticultural crops (Rodino et al., 2014).

Unlike the antibacterial drugs, most of the current antifungal drugs was initially derived from natural sources, for example, Amphotericin B was discovered from *Streptomyces nodosus* (Bacteria), Micafungin was derived from *Coleophoma empetri* (Fungus) and Caspofungin was obtained from *Glarea lozoyensis* (Fungus) (Scorzoni et al., 2016), but most of these antifungal drugs are not consistently effective due to the development of resistance in fungi and the serious side effects of these drugs, so plants that are rich in phytochemicals could represent an excellent source for antifungal drugs (Ahmad et al., 2010).

The geographical position of the Sudan in the center of different Arabian and African cultures helps in building a unique blend of traditional

medical practices, relying mainly on herbal medicine (Khalid et al., 2012). Sudan contains within its borders a great diversity of climatic conditions and vegetation, correlating with these a wide variety of fungi and plant diseases (Omer, 2007). Besides, the critical health situation due to the deterioration of the health care services, has led the majority of the population to depend on the traditional medicinal plants as an alternative for the expensive modern drugs (Abdalla and Abdallah, 2016). However, Sudan possesses an immense wealth of bioactive medicinal plants that is still unexploited. The aim of this review is to highlight about Sudanese medicinal plants, which are screened for their antifungal activity against different fungi. This could be a precursor for a database that will define the current situation of antifungal research in the country and will help in planning the future.

2. Materials and methods

Data collection of medicinal plants screened for antifungal activity in Sudan was carried out during the period March 2016 to July 2016, by reviewing various published studies (Books, review papers, research papers, short communications, etc.) and unpublished MSc and PhD theses in Sudanese universities. The major scientific databases were searched, such as Google scholar, Science web of Knowledge, Science direct and Pubmed. Some criteria were put in consideration during gathering and tabulating the data of antifungal plants, such as:

- (i) Medicinal plant species which are collected only from Sudan;
- (ii) With reported antifungal activity;
- (iii) Which are investigated in vitro and the method used was mentioned;
- (iv) Full information about the target plant were explained, such as the plant family, the scientific and vernacular names (which are usually used by the local people instead of the scientific names), the tested part of the plant and the solvent used in the extraction of the active constituents;
- (v) Based on literature, the fungi tested against Sudanese plants were *Aspergillus niger*, *A. flavus*, *A. fumigatus*, *Candida albicans*, *Fusarium oxysporum*, *F. culmorum*, *F. graminearum*, *Penicillium italicum*, *P. digitatum*, *Phialophora richardsiae*, *Trichophyton verrucosum*, *T. rubrum*, *T. concentricum*, *T. tonsurans*, *T. mentagrophytes*, *Microsporum canis*, *M. audouinii*, *Saccharomyces cerevisiae*, *Madurella mycetomatis*, *Epidermophyton floccosum*.
- (vi) For facilitation, the antifungal efficacy of the target plants was expressed as (+) which means presence of antifungal activity, or as (-) which means absence of antifungal activity, based on the researcher statement.

3. Results and discussion

As shown in Table 1, detailed information about the plants and their antifungal properties are presented. It was revealed that, up to 85 plant

species belonging to 48 families (42 dicotyledonous and 6 monocotyledonous) were reported to have antifungal activity against some fungal species.

It was shown in Fig. 1 that Fabaceae, being represented by 10 species, was the most family tested for antifungal activity, followed by Asteraceae (5 species), Brassicaceae, Capparaceae and Malvaceae (4 species), then Burseraceae, Combretaceae and Euphorbiaceae (3 species). The rest of families were only represented by either two or one species. The family Fabaceae is considered a large family, divided into three subfamilies represented in this study by: Caesalpinoideae (1 species), Faboideae (6 species) and Mimosoideae (3 species), where subfamily Faboideae still represent the most tested taxon. However, the species *Acacia nilotica* (subfamily Mimosoideae) received the greatest attention of Sudanese researchers for antifungal activity, where 4 parts of this species were tested using different solvents and methods of extraction with a total of 34 tests of this single plant species against different fungal species (Table 1). This attention could be attributed to the wide use of this species in Sudanese traditional medicine (Brown and Massey, 1929; El Ghazali et al., 1987; El Ghazali et al., 1994; El Ghazali et al., 1997) as well as rural tanning industry (Musa and Gasmelseed, 2014).

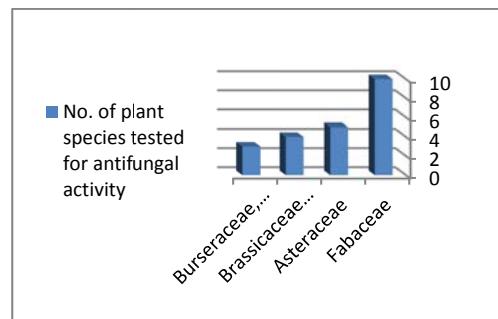

Fig. 1: Number of plant species tested for antifungal activity per family

The main methods used for investigating the Sudanese plants for their antifungal activity in this review, were the cup-plate diffusion method (75.18%), followed by the mean radial growth of mycelium or the dry/wet weight of mycelium (12.7%), the least method used was the disc diffusion method (8%) and the minimum inhibitory concentration method (8%). It was reported that, the main methods for in vitro antifungal screening are diffusion method, minimum inhibitory concentration (MIC), minimum fungicidal concentration (MFC) and IC_{50} value on hyphal growth inhibition as well as many other in vivo and in situ methods (Sasidharan et al., 2012). The majority of these published studies are not funded, reflecting the need to pay more attention and support to the scientific efforts in this developing country, which is rich in medicinal plants.

In addition, systematic and integrated studies on Sudanese medicinal plants in order to discover new antimicrobial drugs are absent; the majority of the studies are at the screening level on crude extracts.

 (+) = presence of antifungal activity,
 (-) = absence of antifungal activity,
 N = Not tested.

In the current survey, the fungi that examined for their sensitivity against the selected Sudanese plants are representing 20 species belonging to 10 genera and 6 families. As shown in Table 1, the fungal genera that were sensitive to these plants were Aspergillus, Candida, Fusarium, Pencillium, Phialophora, Trichophyton, Saccharomyces, Madurella and Epidermophyton. Fig. 2 demonstrated that the majority of the Sudanese plants were tested against the genera Aspergillus and Candida. There is no clear reason behind why researchers gave these two genera more attention in their investigations, however, authors suggest three possible reasons: 1-

these two genera are randomly selected for screening studies; 2-these two genera are easy for culturing; 3- Aspergillus was chosen as a typical fungus with much medical and commercial importance; while Candida was chosen as a typical yeast causing many superficial infections in human.

Accordingly, lots of research efforts are required to evaluate the antifungal activity of these plants against as much as possible of fungi, molds and yeasts particularly the parasitic and saprophytic ones in order to determine the antifungal properties which may lead to the discovery of new antifungal agents.

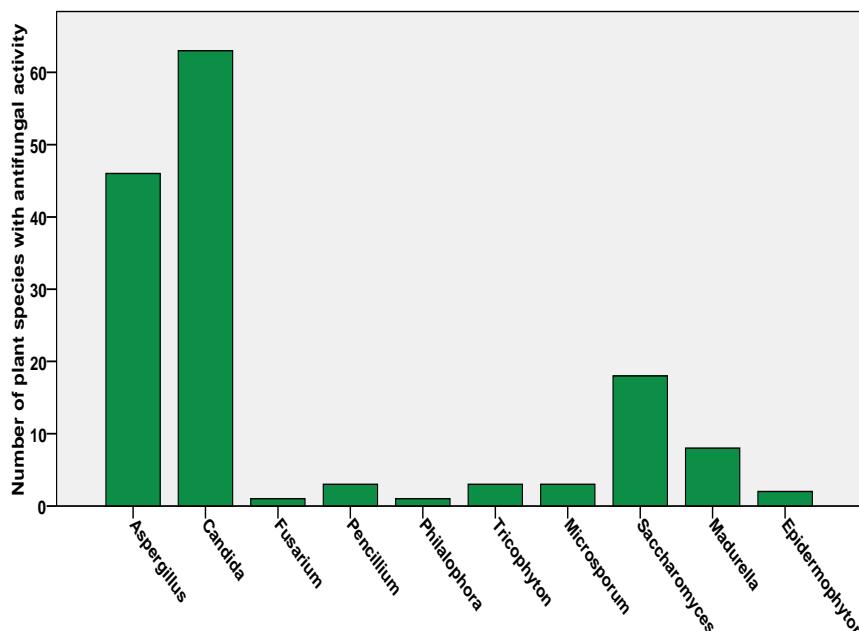

Fig. 2: The number of Sudanese plant species tested for antifungal activity compared with the screened fungal genera

4. Conclusion

Discovering antifungal agents from natural products remains the safer and cheaper solution for many health problems in developing countries. Systematic and more organized antifungal research is needed in Sudan to overcome the poor health situation in the country.

Conflict of interest

The authors declare that there is no conflict of interest regarding the publication of this paper.
